Faster, Sparser, Smaller - Posterized Wavelet Noise Filtering by Huang, X-Chen We are considering estimating image features in a series of images with the same target object, as measured by human observers. Applying post-erosion to image features by averaging across the series is inefficient. Posterization is a sparser, smaller representation of such features. We propose here a joint and adaptive post-erosion and posterization in image space, as a prior in Bayesian image restoration and simultaneous image appearance modeling. We formulate a joint prior and show that it is flexible and can be tuned for a particular application. Our experimental results show improvement in image features by posterization compared with previous methods. A single-channel display of the irradiance over the visible spectrum was developed for use with a digital instrument for measuring color. The instrument performed a full radiance integration across the 400-700 nm range in one channel, allowing detection of a small change in reflectance with a small change in iris diameter. Absolute reflectance obtained by spectral radiance integration is compared with that obtained by colorimetric methods. An absolute reflectance measurement is necessary for accurately comparing color changes due to spectral reflectance changes. An understanding of the effects of the instrument's overall spectral sensitivity also is necessary. This video is part of the following collection of related videos: An eight-channel display of the irradiance over the visible spectrum (400-700 nm) was developed for use with a digital instrument for measuring color.
